IMPROVING PRODUCTIVITY AND GRAIN NUTRITIONAL QUALITY OF WHEAT (**Triticum aestivum**) UNDER DROUGHT STRESS CONDITION BY COMBINED NPK FERTILIZATION

Mohammad Safar Noori, Hirofumi Saneoka

Graduate School of Biosphere Science, Hiroshima University, 1-4-4 Kagamiyama, Higashi-Hiroshima, 739-8528, Japan

ABSTRACT

Drought stress is a major threat that retards plant growth, reduces grain yield and affects grain quality. The present study was conducted to ascertain the effect of combined application of nitrogen (N), phosphorus (P) and potassium (K) fertilizers on productivity, and nutritional quality of wheat under drought stress conditions. Wheat cultivars MinaminoKaori and Lalmi-2 were grown in pots in a greenhouse, and subjected to 3 levels of NPK fertilizer applications. Then the plants were exposed to 2 levels of drought stress and well-irrigated control at grain filling stage. The result of this study indicated that drought stress significantly decreased grain yield, grain starch content, and water-soluble pentosan content, but increased grain crude protein content, total pentosan content, and phytate phosphorus content of both cultivars. Lalmi-2 exhibited a greater tolerance to drought conditions, by higher grain yield, and higher total K and starch contents under both well-irrigated and drought stress conditions than MinaminoKaori, while MinaminoKaori recorded higher grain mineral concentration, crud protein, total pentosan, water-soluble pentosan and phytate phosphors content than Lalmi-2. It was suggested that increase in rate of NPK fertilization could ameliorate the adverse effects of drought stress and enhance plant productivity, and concentrations of minerals, crude proteins and water-soluble pentosan in the grain under drought stress conditions. Besides applying higher rates of NPK fertilizers, it is suggested that use of fertilizer responsive and drought-tolerant genotypes such as Lalmi-2 will be beneficial to minimize the risk of yield loss due to drought stress.

Keywords: Wheat, Phytate phosphorus, Pentosans, Starch, NPK, Crud protein

1. INTRODUCTION

Drought is a limiting factor that adversely affects wheat productivity, and reduces plant growth by influencing several vital processes in plants, such as transpiration, translocation, mineral
uptake and the metabolism of nutrients (Farooq et al., 2009). Crop production limitation rising from drought stress might be increased in the upcoming decades due to climatic change which may reduce precipitation and accelerate evapotranspiration (World Bank, 2007; Lobell et al., 2008). Under drought stress conditions, plant water potential and turgor decrease greatly, and therefore normal physiological functions cannot be performed (Zhu, 2002). Drought stress affects adversely on leaf growth (Galle et al., 2010), leaf chlorophyll concentration (Brevedan and Egli, 2007), stomatal conductance (Liang et al., 2002), and therefore it reduces photosynthetic activity and speed up leaf senescence (Yang and Zang, 2006) which eventually results in declined growth and yield of crops (Ercoli et al., 2007). Plant survival or death under stress conditions, depends on severity of stress, duration and frequency of exposures, plant developmental stage, organ or tissues that expose to stress, and genetic characters (Larkindale et al., 2005; and Farooq et al., 2009). Yang and Zang (2006) concluded that wheat is highly sensitive to drought stress during flowering and grain filling stages.

Increased doses of nitrogen (N) improved drought tolerance (Halvorson and Reule, 1994). N fertilization mitigates the adverse effects of drought stress on plant growth by improving water use efficiency (Saneoka et al., 2004). It also enhances leaf area and leaf chlorophyll content and thus improves photosynthetic efficiency and reduces photo-damage under drought stress conditions (Wu et al., 2008). Phosphorus (P) fertilization effectively promotes plant growth under drought stress by enhancing root growth (Singh and Sale, 1998), increasing water use efficiency (Garg et al., 2004; and Waraich et al., 2011) increasing leaf area and photosynthetic activity (Singh et al., 2006), maintaining leaf stomatal conductance and nitrate reductase activity (Bruck et al., 2000; and Naeem and Khan, 2009) and increasing cell-membrane stability and water relations (Sawwan et al., 2000; and Kang et al., 2014). Application of adequate level of potassium (K) enhances water use efficiency (Egilla et al., 2005), photosynthetic activity, plant growth and yield in different crops under drought stress conditions (Tiwari et al., 1998; and Egilla et al., 2001). K fertilization alleviates detrimental effects of drought stress by improving many physiological processes such as regulation of turgor pressure and photosynthesis, enzymes activation and translocation of cations (Mengel and Kirkby, 2001). Marschner (2012) concluded that K⁺ as an inorganic osmotica, plays a significant role in formation of the osmotic adjustment ability, even under drought conditions.

The effects of nutrients such as N, P, and K on enhancing plant growth, grain yield, and grain quality of plants under normal conditions has been well studied so far; however, little is known about their function, if applied in combination, in improving grain yield, grain nutritional quality, pentosans content and phytate P content of wheat under drought stress conditions. Therefore, the present experiment was conducted with the aim to evaluate the effects of combined application
of NPK on growth, productivity, grain minerals, starch, crude protein, total and water-soluble pentosans, and grain phytate P of wheat, under drought stress condition.

2. MATERIALS AND METHODS

2.1 Experiment description

This experiment was designed to evaluate the effect of combined fertilization of different levels of NPK on wheat productivity and grain nutritional quality under late season drought stress conditions. A pot experiment was conducted in the greenhouse of the Faculty of Applied Biological Sciences, Hiroshima University during growing season of 2016-2017. Two wheat cultivars, MinaminoKaori a commonly grown winter wheat in Japan and Lalmi-2 a facultative bread wheat grown in rainfed lands of Afghanistan were used in this study. The experiment was carried out in a vinyl greenhouse with natural sunlight and temperature to prevent nutrient leachate and avoid interruption by rainfall. Pots with capacity of 10 liters (top and bottom diameters of 29 and 25 cm and a depth of 27 cm) were used. They were filled with 10 kg of a mixture of regosol, aerobic compost and vermiculite (2:1:1, v/v). Chemical analysis of this mixture showed that it contained: 0.16 % N, 5.74 mg kg\(^{-1}\) P, and 72.58 mg kg\(^{-1}\) K. Furthermore, (6.4 g pot\(^{-1}\)) of dolomitic calcium magnesium carbonate was mixed with the soil to adjust the pH (H\(_2\)O) to 6.5. The present experiment was designed with 3 levels of NPK fertilizers: F\(_1\) (150 kg N + 100 kg P\(_2\)O\(_5\) + 75 kg K\(_2\)O ha\(^{-1}\)), F\(_2\) (200 kg N + 120 kg P\(_2\)O\(_5\) + 100 kg K\(_2\)O ha\(^{-1}\)), and F\(_3\) (250 kg N + 140 kg P\(_2\)O\(_5\) + 125 kg K\(_2\)O ha\(^{-1}\)). The sources of N, P and K were urea, single super phosphate (SSP), and potassium sulfate, respectively. They were applied in pots, as F\(_1\) (2g urea+3.76 g SSP+0.96 g potassium sulfate pot\(^{-1}\)), F\(_2\) (2.8g urea+4.51 g SSP+1.28 g potassium sulfate pot\(^{-1}\)) and F\(_3\) (3.5g urea+5.3 g SSP+1.6 g potassium sulfate pot\(^{-1}\)). All of P and K, and a half dose of N were applied before sowing, and the remaining N was applied in two equal splits at the time of tillering and anthesis stages. Wheat seeds were sown in the middle of November 2016. 15-day-old seedlings (2 plants pot\(^{-1}\)) were transplanted in the pots, and the pots were arranged in a randomized complete block design with 4 replications. The plants were irrigated with tap water regularly until imposing the drought stress. Drought treatments consisting of well-irrigated, mild stress and severe stress were applied during the grain filling stage. The soil water content was adjusted to 20%, 10% and 6% for well-irrigated, mild drought stress and severe drought stress conditions, respectively, and monitored by a Time Domain Reflectometry (TDR-341F model, Fujiwara, Japan) digital moisture meter regularly. The drought stress continued for 40 days until the crop reached harvesting maturity. The following parameters were recorded by the time of harvest and thereafter.

2.2 Growth, Yield, and Yield component:
Number of fertile tillers (spike bearer tillers) per plant was counted before harvest. To measure 1000 kernel weight, 500 grains were counted, and weighted with a prescribed accuracy, and then the value was multiplied by 2. To determine the grain yield, mature spikes were collected, oven dried at 80°C for 48 hours, threshed, and the grain yield was recorded and expressed as grams per plant. The harvest index (HI) was calculated using the following formula:

\[ HI = \frac{\text{Grain yield}}{\text{Total above ground biomass yield}} \times 100 \]

2.3 Grain mineral concentrations:

Samples of mature seeds were ground finely with a vibrating sample mill (TI-100, Heiko, Japan). 100 mg of ground samples were digested by sulfuric acid, diluted to 100 ml of distilled water, and K content was measured using a flame photometer (ANA 135, Tokyo Photoelectric, Tokyo, Japan). Total P was determined using the same digested sample by UV-Spectrophotometer (U-3310, Hitachi Co. Ltd. Tokyo, Japan) following the molybdenum reaction solution method suggested by Chen et al., (1956). Total nitrogen was measured using the Kjeldahl method after digestion of ground sample with concentrated H\textsubscript{2}SO\textsubscript{4} and H\textsubscript{2}O\textsubscript{2} (10:5, v/v). Grain Ca, Mg, and Zn concentration were measured by an atomic absorption flame emission spectrophotometer (AA-6200, Shimadzu, Japan). For grain inorganic P (Pi) determination, 10 ml of trichloroacetic acid (12.5%) + MgCl\textsubscript{2} (2 mMol /l) were added to plastic tubes containing 50 mg of ground samples and stirred for 24 hours at 4 °C. The tubes were centrifuged at 7000 rpm under 4 °C temperature, then a specific amount of supernatant was drawn and Pi was measured using a spectrophotometer by the molybdenum reaction regent method (Raboy and Dickinson, 1984).

2.4 Determination of grain starch and crude protein:

For the determination of grain starch, 80% ethanol was added to the powdered samples to remove sugars and then starch was extracted with perchloric acid. Anthrone reagent was added to the test tubes containing extracted samples and then heated in a boiling water bath for 7.5 minutes. The absorbance of the extract was measured at 630 nm (Nag, 2016). Grain crude protein content was calculated by multiplying grain total N content by 5.47 (Fujihara et al., 2008).

2.5 Determination of total pentosan (TP) and water-soluble pentosane (WSP):

Grain TP was measured following the orcinol-HCl method where finely ground samples were hydrolyzed with 2 N HCl in a boiling water bath for 2.5 hours, and then centrifuged. A specific amount of supernatants was transferred to new test tubes and reaction regents (FeCl\textsubscript{3} and Orcinol) were added and vortexed. The tubes were heated in boiling water for 30 minutes,
cooled, and the absorbance was measured using a spectrophotometer. Grain WSP was extracted by hydrolyzing powdered samples in distilled water by shaking for 2 hours at 30°C. Then, 4 N HCl was added to the aliquots of the supernatant and placed in boiling water for 2 hours, and allowed to cool, and WSP was estimated by a spectrophotometer, using FeCl₃-orcinol reagents (Hashimoto et al., 1986).

2.6 Estimation of phytate phosphorus (Phy-P)

Phy-P was measured following the method suggested by Raboy and Dickinson (1984) where aliquots of ground samples were extracted in an extraction media (0.2 M HCl: 10% Na₂SO₄) overnight at 4°C while shaking. Extracts were centrifuged, and phytate P was obtained as a ferric precipitate and assayed for P using ammonium molybdate reaction reagent.

2.7 Statistical analysis

All the collected data were subjected to analysis of variance using SPSS statistics package, Version Student Version 22, and means (n = 4) were separated using the Duncan Multiple Range Test at p = 0.05.

3. RESULTS

3.1 Grain yield and yield components

Statistical analysis of data showed that drought stress significantly reduced the number of fertile tillers, 1000 kernel weight, grain yield and harvest index in both cultivars (Table 1). Application of a high rate of NPK (F₃) resulted in the production of a higher number of fertile tillers in both cultivars under well-irrigated conditions, while F₁ treatment recorded the lowest number of fertile tiller in MinaminoKaori cultivar under severe drought stress conditions. F₃ treatment enhanced the production of fertile tillers in both cultivars under mild and severe stress conditions. Cultivar Lalmi-2 recorded higher number of fertile tillers under all levels of NPK and drought stress treatments compared to that of MinaminoKaori. The 1000 kernel weight was significantly different between cultivars, NPK treatment levels and drought stress levels. Cultivar Lalmi-2 recorded higher 1000 kernel weight under all levels of NPK fertilization and drought stress conditions compared to MinaminoKaori. NPK treatments slightly increased 1000 kernel weight in MinaminoKaori under all levels of drought stress levels however, the mean values did not differ significantly. F₃ and F₂ treatments recorded the highest 1000 kernel weight in Lalmi-2 cultivar under well-irrigated conditions. NPK fertilization significantly increased 1000 kernel weight in Lalmi-2 under all levels of stress conditions. In comparison with F₁, F₃ treatment increased 1000 kernel weight in Lalmi-2 cultivar by 7.7% and 16.8 % under mild stress and severe-stress conditions respectively. In MinaminoKaori, increase
in 1000 kernel weight due to the high rate of NPK (F₃) fertilization was 9.1% under mild stress and 4.75% under severe stress compared to F₁ treatment.

**Table 1.** Average number of fertile tillers per plant, 1000 kernel weight, grain yield and harvest index of two wheat cultivars influenced by different levels of NPK fertilization under drought stress conditions. Means with different letters are significantly different from each other at p ≥ 0.05.

</table>
Grain yield was negatively affected by drought stress in both cultivars. Lalmi-2 recorded higher grain yield under all levels of drought stress conditions compared to MinaminoKaori. NPK treatment significantly increased grain yield. F$_3$ treatment recorded higher grain yield in both cultivars under both drought stress conditions. It was observed that mild drought stress had less effect on grain yield of Lalmi-2 cultivar. F$_3$ treatment recorded the highest grain yield in Lalmi-2 under well-irrigated and mild stress conditions. Grain yield was the lowest in cultivar MinaminoKaori under severe drought stress conditions with the lowest NPK fertilizer (F$_1$) level. F$_3$ treatment increased grain yield by 38.2% under mild stress and 24.0% under severe-stress conditions compared to F$_1$ treatment in Lalmi-2 cultivar. However, in MinaminoKaori increase in grain yield due to high NPK (F$_3$) fertilization under mild and severe stress conditions compared to F$_1$ treatment was 29.9 and 35.0% respectively. Harvest index was significantly reduced in MinaminoKaori cultivar under drought stress conditions however, in Lalmi-2 a higher harvest index was observed under mild stress conditions. F$_3$ treatment increased harvest index in both cultivars. The highest harvest index was recorded in Lalmi-2 cultivar under mild stress conditions where a high rate of NPK (F$_3$) was also applied. However, F$_1$ treatment recorded the lowest harvest index in MinaminoKaori cultivar under all levels of stress conditions. In comparison with F$_1$, F$_3$ treatment increased harvest index by 14.9% under mild stress condition and 8.7% under sever-stress condition in Lalmi-2 cultivar. In MinaminoKaori cultivar F$_3$ treatment increased the harvest index compared to F$_1$ treatment by 5.2% and 9.2% under mild and severe stress conditions, respectively.

3.2 Grain mineral concentrations

Mineral concentration was highly affected by drought stress and NPK treatments (Table 2). Drought stress increased total N content in both cultivars. MinaminoKaori recorded a higher total N content compared to Lalmi-2. NPK fertilization enhanced total N content in both cultivars. F$_3$ treatment recorded the highest total N content in MinaminoKaori under severe-stress conditions. The lowest total N content was recorded in Lalmi-2 cultivar under well-irrigated conditions where the lowest rate of NPK (F$_1$) was applied. Grain K content was also increased under drought stress conditions. The highest value of grain K content was observed under severe drought stress condition in F$_3$ treatment of cultivar Lalmi-2. NPK treatment enhanced total K content in both cultivars, however the response was greater in cultivar Lalmi-2. The lowest K content was observed in MinaminoKaori cultivar under well-irrigated condition with the lowest rate of NPK (F$_1$) treatment. Grain total P content was recorded higher in MinaminoKaori cultivar under severe drought stress conditions. Grain total P content was greater with F3 treatment under well watered as well as drought stress conditions. MinaminoKaori recorded higher total P content under mild and sever stress conditions than Lalmi-2. F$_1$ treatment recorded the lower total P content in both cultivars under well-irrigated conditions. Drought stress increased Pi
concentration in MinaminoKaori cultivar. Pi content was reduced in Lalmi-2 cultivar due to severe stress conditions. The highest value of grain Pi content was recorded in MinaminoKaori cultivar under severe drought stress conditions with high rate of NPK fertilizer application. F₁ treatment in Lalmi-2 cultivar recorded the lowest Pi content under severe stress condition. NPK fertilization enhanced Mg content and the highest Mg content was observed in MinaminoKaori cultivar with F₃ treatment under severe condition. The lowest Mg content was observed in well irrigated Lalmi-2 with low NPK (F₁) application. MinaminoKaori recorded a higher Mg content under all levels of stress conditions compared to Lalmi-2. NPK fertilization enhanced Ca content and the highest value of Ca was recorded with F₃ treatment in MinaminoKaori under severe stress condition. The lowest Ca content was observed in Lalmi-2 cultivar under severe-stress conditions with the lowest level of NPK (F₁) application. MinaminoKaori recorded a higher Ca content irrespective of NPK treatments and drought stress conditions compared to Lalmi-2. Zn content was found to be higher in MinaminoKaori cultivar irrespective of drought stress and NPK levels compared to Lalmi-2. F₃ treatment slightly enhanced Zn content in both cultivars but the mean values did not differ significantly within the same cultivar. F₃ treatment increased N, K, P, Pi, Mg, Ca and Zn contents in grain by 9.1%, 6.4%, 9.8%, 9.4%, 5.2%, 26.37% and 14.60% compared to F₁ treatment under mild stress respectively, and by 10.1%, 5.1%, 3.1%, 36.4%, 3.0%, 13.2 and 7.5% respectively under severe stress condition in MinaminoKaori. However, in cultivar Lalmi-2, the high level of NPK fertilization (F₃) increased N, K, P, Pi, Mg, Ca and Zn content in grain by 5.1%, 3.6%, 6.3%, 33.5%, 5.1%, 8.4% and 8.5% respectively under mild stress and by 15.2%, 4.1% 7.0%, 31.0%, 1.7%, 15.3% and 6.4% respectively under severe stress condition.

Table 2. Average grain mineral contents in two cultivars of wheat influenced by different levels of NPK fertilization under drought stress conditions. Means with different letters are significantly different from each other at p ≥ 0.05.

3.3 Grain Starch content

Grain starch content decreased by drought stress (Table 3). The highest grain starch content was recorded in cultivar Lalmi-2 under well-irrigated condition, while the lowest was observed in MinaminoKaori under severe stress condition. Grain starch content was decreased with increase in NPK rate. In comparison with well-irrigated condition, mild and severe drought stress decreased grain starch content by 1.5% and 2.6%, respectively in cultivar MinaminoKaori, and by 2.7% and 3.4% respectively in cultivar Lalmi-2.

3.4 Grain crude protein content

Grain crude protein content was increased under drought stress conditions, and the higher crude protein was observed under severe-stress conditions. MinaminoKaori recorded higher crude protein content compared to Lalmi-2 irrespective of NPK levels and drought stress conditions (Table 3). NPK fertilization significantly enhanced crude protein content in both cultivars, and F3 treatment recorded the highest crude protein content in MinaminoKaori under severe-stress conditions. However, the lowest crude protein content was recorded in Lalmi-2 cultivar under well-irrigated condition where the lowest rate of NPK (F1) was applied. In comparison to F1, F3 treatment increased grain crude protein in cultivar MinaminoKaori by 9.1% and 10.1% under mild and severe stress conditions respectively. For the cultivar Lalmi-2 the increase due to high NPK (F3) fertilization was 4.8% and 15.2% under mild and severe stress conditions, respectively.
3.5 Grain TP and WSP content

Grain TP was recorded higher under mild stress condition in both cultivars. Increased levels of NPK (F3) reduced TP content, while low NPK (F1) treatment under mild stress condition resulted in the highest grain TP content in cultivar MinaminoKaori. The lowest TP content was observed in cultivar Lalmi-2 under severe-stress condition where a high level of NPK (F3) was also applied (Table 3). Grain WSP was negatively affected by drought stress conditions. Different from TP, WSP was recorded higher under well-irrigated conditions. F3 treatment resulted in the highest grain WSP content in cultivar MinaminoKaori under well-irrigated conditions. NPK fertilization enhanced WSP content and F3 treatment recorded higher WSP under both levels of drought stress conditions in both cultivars (Table 3). Cultivar MinaminoKaori recorded a higher WSP content under well-irrigated as well as drought stress conditions. Compared to F1, F3 treatment increased grain WSP content in MinaminoKaori by 9.7%, 14.0% and 8.7% under well-irrigated, mild stress and severe stress conditions respectively. These values for the cultivar Lalmi-2 were 11.3%, 13.4% and 22.5%.

Table 3. Starch content, crud protein content, total protein content, water soluble protein content and Phy-P content in grains of two wheat cultivars influenced by NPK fertilization under drought stress conditions. Means with different letters are significantly different from each other at p ≥ 0.05.

3.6 Grain Phy-P content

Drought stress significantly increased grain phy-P content and the highest Phy-P content was recorded under severe stress conditions. NPK fertilization enhanced the accumulation of Phy-P in both cultivars under well-irrigated as well as drought stress conditions. Cultivar MinaminoKaori recorded a higher Phy-P content under severe-stress conditions than cultivar Lalmi-2. F3 treatment recorded the highest Phy-P content in MinaminoKaori cultivar under severe-stress conditions. However, F1 treatment resulted in lower level of accumulation of Phy-P in both cultivars under well-irrigated conditions. F3 treatment increased grain Phy-P content in MinaminoKaori cultivar by 11.0%, 8.9% and 4.1% under well-irrigated, mild stress and severe stress conditions respectively, compared to F1 treatment. These values for the cultivar Lalmi-2 were 3.4%, 3.8% and 3.5%. Severe drought stress increased grain Phy-P content by 10.7% in MinaminoKaori and by 11.3% in Lalmi-2, compared to well-irrigated conditions.

4. DISCUSSION

The results of this study indicated that drought stress adversely affected grain yield and yield components irrespective of NPK treatment levels in both cultivars. Higher levels of combined NPK fertilization improved wheat performance under drought stress condition by enhancing plant productivity, grain mineral concentration, and grain quality. A high rate of NPK (F3) fertilization improved photosynthetic activity by enhancing water and nutrient absorption that resulted in producing more assimilates. As a result increase in number of fertile tillers, 1000 kernel weight, grain yield and harvest index were observed under well-irrigated as well as drought stress conditions. Cultivar Lalmi-2 was more responsive to NPK fertilization and therefore it exhibited greater number of spikes per plant, higher 1000 kernel weight, higher grain yield and increased harvest index under both well-irrigated and drought stress conditions. This
result could be contributed to the genetic potential of Lalmi-2 compared to MinaminoKaori. Ati et al., (2016) concluded that application of NPK fertilizer increased number of spikes and grain yield of wheat under drought stress conditions. Akram et al., (2014) found that application of a higher rate of N improves water use efficiency and enables the plants to survive and thus produce high grain yield under drought stress conditions. Increase in grain yield and yield components of wheat through NPK fertilization under well-watered condition was reported by many researchers (Hussain et al., 2002, Laghari et al., 2010; and Abdel-Aziz et al., 2016), however there is insufficient information on effects of combined application of NPK on wheat yield and yield components under environmental stress conditions including drought.

The grain mineral concentration was significantly influenced by drought stress as well as the level of NPK fertilization and the cultivar differences. It was observed that concentrations of N, K, P, Pi, Mg and Ca in grain were increased under drought stress conditions. Concentrations of minerals in grains were significantly increased with an increase in NPK rate with an exception of Zn. Drought stress induced leaf senescence (Sarwat et al., 2013), and therefore minerals might be transported from leaves to the meristematic tissues and developing grains. The increase in N content in plants under drought stress is due to accumulation of free amino acids that are not synthesized into proteins (Alam, 1999). Under drought stress conditions, most of the N and P was accumulated in grains (Patel and Singh, 1998). F3 treatment in our study consisted of a high rate of N, P and K fertilizers that enhanced N, P, K concentrations in wheat grains. Raza et al., (2013) reported that application of a high dose of K, improved K, N, P and Ca uptake of wheat under drought stress condition. In this study, it was found that grain Pi content was increased under drought stress conditions. The effect of drought stress and NPK fertilization on grain Pi concentration was not sufficiently reported, however a positive relationship was observed between total P and Pi concentration in this study, which could be a reason for a high Pi concentration. P uptake is enhanced when the dose of P fertilizer was increased (Bolland et al. 1999; and Saha et al., 2014). Grain Mg concentration was higher in MinaminoKaori cultivar under well-irrigated and mild stress conditions, however it was lower under severe drought stress condition. F3 treatment recorded a higher Mg content under well-irrigated and mild stress conditions in both wheat cultivars. Slamka et al. (2011) concluded that N fertilization exhibits more expressive effect on plant Mg uptake under optimal water supply conditions. Cultivar MinaminoKaori recorded higher Zn concentration compared to Lalmi-2 irrespective of drought stress and NPK treatments. It could be assumed that Lalmi-2 produced a higher grain yield compared to MinaminoKaori and thus grain Zn concentration was decreased in Lalmi-2.

Drought stress significantly reduced grain starch content in both cultivars. This reduction was due to the adverse effects of drought stress that decreased plant photosynthetic activity, and therefore carbohydrate formation and accumulation of starch was declined. Drought stress during
anthesis and grain filling remarkably decreases starch content of wheat (Saeedipour, 2011). The starch content was decreased with increase in the rate of NPK fertilization. Lalmi-2 cultivar recorded higher starch content and low crude protein compared to MinaminoKaori. Kindred et al. (2008) observed a negative relationship between crude protein and starch content, and N fertilization decreased the starch content of wheat grain. Hlisnikovsky and Kunzova (2014) also found a higher grain starch content in control plants where fertilizer was not applied.

In this study grain crude protein content was enhanced under drought stress conditions, and an elevated level of NPK fertilization greatly increased the crude protein content under both well-irrigated and drought stress conditions. Under well-irrigated conditions, grain protein content may decrease by dilution of N with carbohydrates (Guttieri et al., 2005). Singh et al. (2012) also observed a significant increase in protein content of wheat grown under rainfed conditions. NPK fertilization increased the synthesis of the raw protein in wheat (Crista, 2012). A high level of NPK fertilization enhanced grain crude protein content in the wheat variety Inqulab 91 (Sameen et al., 2002). In our study, F3 treatment consisted a high level of N and K fertilizers that resulted in a higher crude protein content. Many researchers have found that adequate amount of K fertilization improves plant N uptake and protein synthesis (Alam et al. 2009; Lakudzala, 2013; Daniel et al., 2016). Lalmi-2 recorded a lower grain crude protein content compared to MinaminoKaori, and it might be due to the higher yield capacity of Lalmi-2 cultivar and varietal difference in uptake of N and protein synthesis.

Grain TP content was increased under mild drought stress condition. However, a higher level of NPK fertilization slightly decreased TP content in both cultivars under both levels of drought stress conditions. It was assumed that under drought stress, plants produced less grain yield, and most of the non-starch polysaccharides were accumulated in these grains. Effect of NPK fertilization on grain TP and WSP under drought stress conditions in wheat, has not been reported sufficiently by earlier research studies. The result of this investigation indicated that WSP content was reduced under drought stress conditions and NPK fertilization significantly increased WSP content under both well-irrigated and drought stress conditions. Water-unextractable pentosan had a negative effect, while water-soluble pentosan had a positive impact on the bread-making quality of wheat (Courtin and Delcour, 2002).

Phy-P serves as seed storage for phosphorus, but this compound can contribute to a nutritional problem, since it binds with proteins and some important micronutrients, such as Fe and Zn, and significantly reduces their availability (Rosa 1999; and Raboy, 2001). In this study, grain Phy-P content was increased with severity of drought and increased rate of NPK fertilization. The effect of NPK fertilization on the Phy-P content of wheat grain under drought stress conditions was not sufficiently reported by other researchers so far. Phy-P is the major storage form of P in cereals, therefore the concentration of this antinutrient compound mostly depends on the grain total P
content. Application of a high rate of P fertilizer may result in a high phytate content (Raboy and Dickinson, 1984). The reason for a higher Phy-P synthesis and accumulation in wheat grains in F3 treatment may be contributed to the higher rate of P fertilizer application.

5. CONCLUSION

In this study, drought stress significantly reduced grain yield and negatively affected grain nutritional quality of both wheat cultivars by increasing anti-nutrient compound such as grain phytate P content. Drought-induced variation in grain yield and yield components was smaller in cultivar Lalmi-2 than MinaminoKaori. Cultivar Lalmi-2 maintained high grain yield, starch content, and total K content under all levels of stress conditions, while, MinaminoKaori recorded higher grain minerals, crude protein, total pentosan, water-soluble pentosan and phytate P content. A higher rate of NPK fertilization found to be an effective approach that attenuates the deleterious effects of drought stress by improving wheat productivity, and nutritional quality under drought stress conditions.
